1620 DIAGNOSTICS  
CU02 ERROR CHECKS

A. SCOPE:

This fault detection test is designed to check for the proper functioning of the VRC circuits. Information that should force a VRC is presented to the various checking circuits, and an error typeout, including the routine number, occurs if the proper check light is not turned on. Since the circuits involved in each routine are known, the error typeouts indicate those circuits that are not performing properly. Several typeouts may indicate that only a certain bit configuration does not force a VRC; thus further isolating the defective component(s).

B. SETUP:

CHECK SWITCH Settings:

1. DATA CHECK - PROGRAM
2. OVERFLOW CHECK - PROGRAM
- \* 3. CE SW 9 - BYPASS (CE REMOTE START MUST BE USED)

CONSOLE SENSE SWITCH Settings:

These four switches should be set as desired. SUGGESTED SETTING- ALL OFF. These switches have the following functions:

SWITCH #1	ON	Bypass error typeout
	OFF	Type out routine number on error
SWITCH #2	ON	Loop in routine
	OFF	Continue to next routine
SWITCH #3	ON	Stop on error
	OFF	Bypass HALT in error routine
SWITCH #4		NOT USED

NORMAL LOAD FROM TAPE READER

1. Set CHECK and CONSOLE SENSE SWITCHES as SUGGESTED.
2. Load paper tape into reader with REEL mode selected and READY reader.
3. Perform the following operations at the 1620 console:
  - \* On A suffix machines set mar check SW to Program - there is no CE SW 9.

PN 2128303  
EC 404618

NORMAL LOAD FROM CARD I/O:

1. Set check and console sense switches as suggested.
2. Reset 1620.
3. Add two blank cards behind the last card in deck. Place the card deck in the read hopper and depress the load key.

These constants for MAR check of memory capacity are automatically inserted by the program.

1. For 20 K 23456789≠
2. For 40 K 456789≠
3. For 60 K 6789≠
4. For machines with 1311. 6789 +

R - S

C. TEST METHOD

The information in the tape is first loaded into memory. After all instructions are loaded, the program branches to the first instruction (memory location 00828) of the first routine which types out the setting of the console switches, the instruction to set the switches as desired and then halts. Following the typed out instructions, depression of START causes the machine to branch to 04548. Further instructions are typed out. Constants used in the routine that tests the ability of MAR to detect a too large address must be keyed in, followed by a record mark.

Depressing RELEASE terminates the read instructions, and START initiates a branch operation that will send the program to routine 002 after typing out that the routines have been started.

Routine 002 resets all VRC circuits (RC, WC, MBR E, MBR O, MAR) and then checks that any latch is off.

1620 DIAGNOSTICSCY02 ERROR CHECKS

Routine 003 forces a MBR-E VRC by calling for a read alpha to an even position of memory. On a properly programmed read alpha operation the zone portion of the character is read into MBR-E and the numeric portion is read into MDR. If the read alpha operation is addressed to an even portion, both the zone and the numeric portion are read into MBR-E and nothing is read into MBR-O.

The ten characters used to force the MBR-E VRC are: )A+/- B K Q Y 8. The bit configurations resulting from the read alpha to an even memory address and the respective addresses are as follows:

Address	Bit Configuration
01272	C and 4
01274	1 and 4
01276	C and 1
01278	C and 2
01280	1 and 2
01282	2 and 4
01284	C, 1, 2, and 4
01286	C, 1, 4, and 8
01288	C, 2, 4, and 8
01290	1, 2, 4, and 8

Routine 004 checks that these ten bit configurations will force a MBR-O VRC. An instruction to transmit the specific digit to an odd memory position is used to force the VRC. The odd memory positions to which these "digits" are sent are 01665, 01667, 01669, 01671, 01673, 01675, 01677, 01679, 01681, 01683.

Routine 005 uses eight of these bit configurations to check that they will force a WC VRC. The other two configurations are not used; as any configuration that contains bits 2-8 will cause the typewriter to hang up on a write numeric operation. The last two configurations are not used.

Routine 006 checks that a record mark will force a MAR VRC. This is checked for all five positions of MAR.

Routine 007 checks that a MAR VRC is forced by the invalid bit configuration generated by the read alpha operation. These bit configurations are checked in the low order position of MAR, then in the tens position of MAR, and on up until they have checked the ten thousand position of MAR.

Note: An Error Typeout for routine 007 will be as follows:

H007 0291x $\bar{y}$

where "x" = 5 indicates the error occurred in the units position of the address  
 = 4 indicates the error occurred in the tens position of the address  
 = 3 indicates the error occurred in the hundreds position of the address  
 = 2 indicates the error occurred in the thousands position of the address  
 = 1 indicates the error occurred in the ten thousands position of the address

and 012yy is the address of the invalid character which caused the error (see routine 003 description).

1620 DIAGNOSTICSCU02 ERROR CHECKS

Routine 008-011 check that ANY latch is turned on by an MBR-E, MBR-O, and WC VRC.

Routine 012 checks that an address sent to MAR that is larger than the memory capacity of the machine will force a MAR VRC. The constants used for this test must be keyed in at the beginning of this test

Routine 013 is the routine that repeats the above routines twenty times before proceeding to the next routine.

Loader - The loader used in the object decks of this test is of a simplex type which uses just a read and branch. (Tapes are loaded completely with a single instruction) there are two types of cards in the object deck, Loader cards and data cards. The cards alternate through the whole deck. The data cards consist of 75 columns of data and 5 columns for a sequence number. The loader card is set up as follows:

Columns 1-12	36	xxxxx	00500
Columns 13-24	36	00000	00500
Columns 25-36	49	00000	00000
Columns 37-48	39	00051	00100
Columns 49-75	48	42007	479004641095345440#0
		I B	49 failed in numeric 1
Columns 76-80		Sequence	number

The first instruction reads a data card into core storage. The second instruction reads a new load card over the one already in core. The next instruction (which is from the load card just read) branches back to start the cycle all over again. If the branch to 00000 fails, B 49 failed is typed out.

The last load card has a branch to the start of the program in place of the second read instruction.

Routine 014 checks that an invalid character in the tape will force a RC VRC and that this will turn on ANY LATCH.

The complete normal typeout information will be as follows:

(NOTE: The numeric constants keyed in will be determined by the storage capacity of the machine.)

SW 1 OFF SW 2 OFF SW 3 OFF SW 4 OFF SET SWS FOR CU02.  
THEN START. KEY IN CONSTS FOR MAR ADDRESS TEST. RELE  
ASE, START.

(00828)

CU02 FLOW CHART  
WITH 1622 I/O

This routine will indicate whether BI and/or BNI codes are working properly. The 1620 will Halt with 01091 in MAR.

The machine will stop calling for a read from the keyboard. For:

- 1.) 20K memory - key in 23456789≠
- 2.) 40K memory - key in 456789≠
- 3.) 60K memory - key in 6789≠

From Routine 002  
(01260)

01272 to 01596

Routine 003  
Generate Invalid  
parity characters by  
read alpha to even  
position of memory.  
Forces MBR-E VRC  
Branch to 01764

Ten invalid characters are generated from the following legitimate characters )A/-/BKQY8. Invalid characters read into memory locations 01272, 01274, 01276, 01278, 01280, 01282, 01284, 01286, 01288, 01290.

01596 to 02136

Routine 004  
Force MBR-O VRC.  
Transfer invalid char.  
generated in Routine 3  
to an odd memory  
position  
Branch to 02208

From times 20  
Repeat Routine  
NO O'FLOW.  
(04188)

Odd memory positions are 01665, 01667, 01669, 01671, 01673, 01675, 01677, 01679, 01681, 01683. Invalid characters are: C 1 C C 1 2 C C C 1  
4 4 1 2 2 4 1 1 2 2  
2 4 4 4  
4 8 8 8

02136 to 02412

Routine 005  
Force WC VRC  
write numeric on  
typewriter  
Branch to 02488

Invalid characters read from memory positions 01665, 01667, 01669, 01671, 01673, 01675, 01677, 01679. Note: A RM bit configuration (2-8) will cause the typewriter to hang up on a WN operation; therefore, characters in 01681 and 01683 are not sent to the typewriter. Type out will be ~~4512367~~

02412 to 02700

Routine 006  
Force MAR VRC  
with RM. Check all  
positions of MAR  
Branch to 02796

One position of OR-1 contains RM, others are ones.

02700 to 03120

Routine 007  
Force MAR VRC with  
invalid parity  
character.  
Branch to 03120

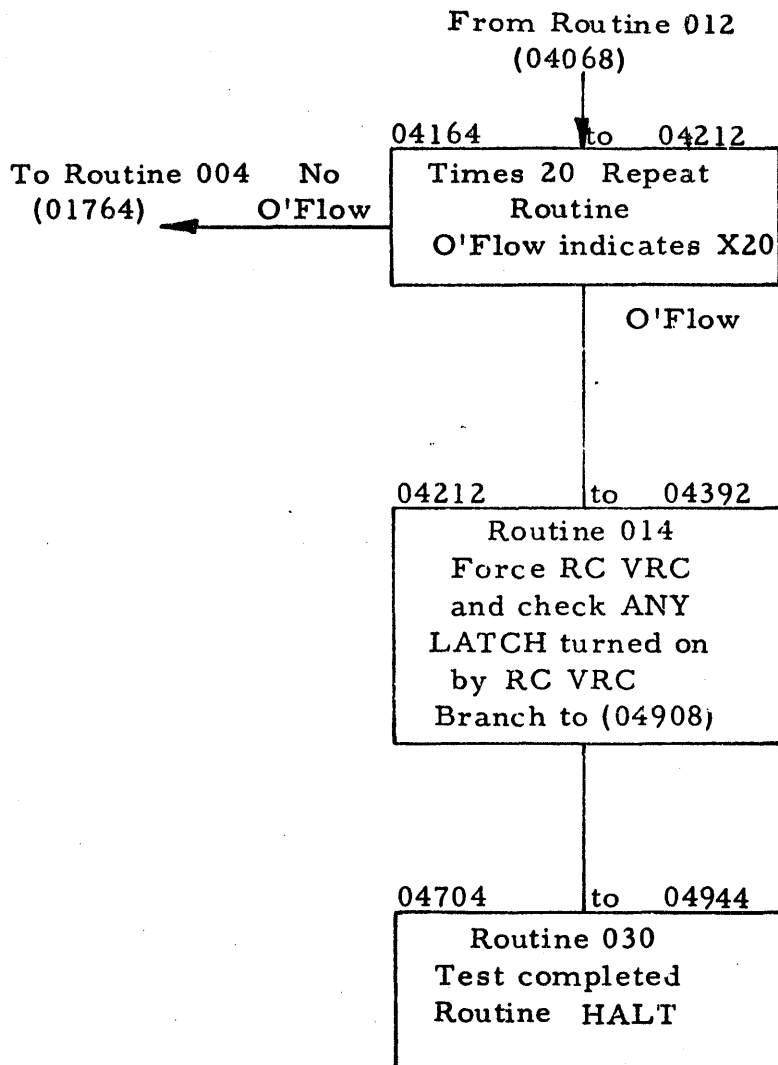

Invalid parity characters force a MAF VRC before proceeding to check of next high order position of MAR. Invalid characters taken from 01276, 01278, 01280, 01282, 01284, 01286, 01288, 01290.

To Routine 008  
(03120)

This routine will cause an invalid character (\*) to be typed.

For this routine to be performed correctly, constants must have been keyed in at beginning of test.

Invalid character in paper tape is  
Bit combination 2C.  
This routine is bypassed  
with card I/O
